

Lab 8 Report

Basic Information

- Name: Richard (Yunchao) He
- Report document:
<https://docs.google.com/document/d/1kREgQaE-70tBFT-3ILi7qZtRUuWOk42jppuSpoNnYal/edit>

Screenshots

- Screenshots showing both ASL gestures correctly identified by the Arduino Serial Monitor.
 - In my experiment, the ASL gesture “Hi” is much easier to be recognized by the model. And the confidence score is very high by softmax, which is above 0.9 sometimes.

```
lab8-classifier-dual-board | Arduino IDE 2.3.10

Output Serial Monitor X
Message (Enter to send message to 'Arduino Nano 33 BLE' on '/dev/cu.usbmodem1101')
Accelerometer sample rate = 99.84 Hz
Gyroscope sample rate = 99.84 Hz
hi: 0.924491
sup: 0.075509
hi: 0.756676
sup: 0.243324
hi: 0.797016
sup: 0.202984
hi: 0.792511
sup: 0.207489
hi: 0.825613
sup: 0.174386
hi: 0.858440
sup: 0.141560
hi: 0.804392
sup: 0.195608
hi: 0.869992
sup: 0.130008
hi: 0.927737
sup: 0.072263
hi: 0.930058
sup: 0.069942
hi: 0.885603
sup: 0.114397
```

- However, “Sup” (what’s up) is not that easy to be recognized. The highest confidence score by the model (from my deployment data only) is around 0.69 by softmax.

Software Issue

Software issue fixed

- A brief explanation of the software issue I fixed in the notebook
 - The original model was compiled using mean squared error (mse) as the loss function and mean absolute error (mae) as the evaluation metric. These settings are more appropriate for regression tasks, while this lab performs categorical classification with one-hot encoded labels and a softmax output layer. I changed the loss function to `categorical_crossentropy` and the evaluation metric to `accuracy`.
 - The code changes is actually tiny (marked in a blue rectangle in the figure below)

```
[6]: # Build the model and train it.
model = tf.keras.Sequential()
model.add(tf.keras.layers.Dense(50, activation='relu')) # ReLU is used for performance.
model.add(tf.keras.layers.Dense(15, activation='relu'))
model.add(tf.keras.layers.Dense(NUM_GESTURES, activation='softmax')) # Softmax is used because only one gesture is expected per input.
# model.compile(optimizer='rmsprop', loss='mse', metrics=['mae'])
model.compile(
    optimizer='rmsprop',
    loss='categorical_crossentropy',
    metrics=['accuracy']
)

history = model.fit(
    inputs_train,
    outputs_train,
    epochs=100,
    batch_size=16,
    validation_data=(inputs_validate, outputs_validate),
)

print("History keys:", list(history.history.keys()))
```

Downstream consistency changes

- A brief explanation of the downstream consistency changes
 - In order to keep the downstream evaluation and plots consistent with the corrected training configuration, I changed `METRIC_TO_PLOT` from `mae` to `accuracy`. As a result, the notebook now reads the `accuracy` and `val_accuracy` history values and labels the training plot accordingly.
 - The code change is pretty small, see the blue rectangle in the figure below

```
[9]: # METRIC_TO_PLOT = "mae" # Update this if you changed the metric used during training.
    METRIC_TO_PLOT = "accuracy"
    VAL_METRIC_TO_PLOT = f"val_{METRIC_TO_PLOT}"

    metric_values = history.history[METRIC_TO_PLOT]
    val_metric_values = history.history[VAL_METRIC_TO_PLOT]

    plt.figure(figsize=(12, 5))
    plt.plot(epochs[SKIP:], metric_values[SKIP:], label=f"Training {METRIC_TO_PLOT}")
    plt.plot(epochs[SKIP:], val_metric_values[SKIP:], label=f"Validation {METRIC_TO_PLOT}")
    plt.title(f"Training and Validation {METRIC_TO_PLOT}")
    plt.xlabel("Epoch")
    plt.ylabel(METRIC_TO_PLOT)
    plt.legend()
    plt.grid(True)
    plt.show()
```

Other change

The lab mentioned **quantizing** the model for tinyML. So, I attempted post-training optimization using `tf.lite.Optimize.DEFAULT`, which reduced the model size from 148,296 bytes to 41,296 bytes via **INT8 quantization for model parameters** (not including input/output data). However, the resulting hybrid model was not supported by the TensorFlow Lite Micro fully connected kernel on the Arduino. Although compilation and upload succeeded, model initialization failed during `AllocateTensors()`. I therefore reverted to the FP32 TFLite model, regenerated `model.h`, and successfully deployed and tested it.

See the commented code snippet below in blue rectangle:

```
[12]: converter = tf.lite.TFLiteConverter.from_keras_model(model)

    # Enable TensorFlow Lite model optimization and quantization.
    # converter.optimizations = [tf.lite.Optimize.DEFAULT]

    tflite_model = converter.convert()

    tflite_path = BUILD_DIR / "gesture_model.tflite"
    tflite_path.write_bytes(tflite_model)

    print(f"Saved: {tflite_path}")
    print(f"TFLite model size: {tflite_path.stat().st_size:,} bytes")
```
